AN INSTANCE OF HYDATIDS DISCHARGED
FROM THE UTERUS.

Reported by J. WEARNE, Esq., M.R.C.S. and L.S.A.,
Cornwall.

M. C—, aged thirty-six, married, and the mother of eight
children, had supposed, four months ago, from the discon-
tinuance of the menstrual discharge and from her increasing
size, that she was again enceinte. But about a month ago,
there occurred a somewhat free discharge of blood from the
vagina, and she expected that she was about to abort. With
occasional yet exhausting recurrences of uterine hæmorrhage,
the case went on till the 24th of July, on which day I was
requested to see her, with the gentleman who had been in
attendance up to that time. She was then in a pallid,
emaciated condition; pulse 120; vomiting occasionally; had
been unable to retain food for several days; a small but
steady discharge of blood still persisting; exhaustion not so
great, but she preferred the sitting posture in bed.

On examining the abdomen, I found that it was distended,
and I also observed that the feet were œdematous. With
respect to the tumidity of the abdomen, it was observable,
however, that it did not extend from one ilium to the other,
but that on each side a sulcus existed between the tumour
and the bone. The tumour, also, was inelastic, omental-like,
more solid than water, scarcely at all fluctuating on percus-
sion, and with none of the hard irregularities which might
indicate foetal contents.

On passing my finger into the os uteri, I found it dilated to
a little more than the size of a shilling. If anything could be
said to present, it was uncertain whether it might be coagu-
lated blood or softened placenta; I am inclined to believe it
was the former.

When I left, I recommended Mr. Sargent, her surgeon, to
examine her occasionally, although the uterine pains were
almost imperceptible; and in case of any presentation at the
os uteri, to give the ergot, to facilitate the discharge of the
uterine contents. I heard no more of her case till the next
day, when her husband came to me with a cupful of hydatids,
and assured me that his wife discharged no less than four
or five quarts of them in a short time after my visit on the
preceding day.

I have before seen cases of uterine hydatids, but generally
after such discharge had commenced; but in this instance I have been enabled to watch and detail the preliminary appearances and symptoms, which I have thought it best to send to you for the benefit of those who may not yet have had the same opportunity.

Helston, Cornwall, 1853.
